Random Testing Quiz Documentation

For inputChar() it was straightforward to set up a range of ASCII characters with rand() that I wanted to use for the generator. I looked up an ASCII table to make sure I was including the characters I wanted to use. Initially I felt I included too many so I ended up reducing the range to just wide enough to include all the special characters that the base program would be searching for to proceed to the next "state".

For inputString() at first I was using the same range of characters for inputChar without thinking, but realized that the base program was only looking for a very small range (characters 'e' through 't'). I then set it so that the final character would be '\0', the terminating character that the base program searches for.
